Package 'doseminer'

October 13, 2022

Type Package

Title Extract Drug Dosages from Free-Text Prescriptions

Version 0.1.2

Description
Utilities for converting unstructured electronic prescribing instructions into structured medication data. Extracts drug dose, units, daily dosing frequency and intervals from English-language prescriptions. Based on Karystianis et al. (2015) <doi:10.1186/s12911-016-0255-x>.

R topics documented:

`clean_prescription_text` *Clean up raw prescription freetext*

Description

Clean up raw prescription freetext

Usage

```
clean_prescription_text(txt)
```

Arguments

`txt`	a character vector

Value

a character vector the same length as `txt`

Examples

```
clean_prescription_text(example_prescriptions)
```

cprd *Sample electronic prescribing dataset*

Description

A dataset containing product codes, patient identifiers, quantities, dates and free-text dose instructions, similar to data provided by the Clinical Practice Research Datalink (CPRD).

Usage

```
cprd
```

Format

An object of class `data.frame` with 714 rows and 6 columns.

Details

Variables in the data include

id record identifier

patid patient identifier

date date of start of prescription

prodcode product code; identifier for the prescribed medication

qty total quantity of medication prescribed

text free text prescribing instructions

drug_units *Medication dosage units*

Description

A named character vector. Names represent patterns to match dose units and values represent standardised names for those units.

Usage

```
drug_units
```

Format

An object of class `character` of length 28.

Details

Use with a function like `str_replace_all` to standardise a freetext prescription. Used internally in `extract_from_prescription`.

example_cprd *Example freetext prescriptions*

Description

Adapted from CPRD common dosages

Usage

```
example_cprd
```

Format

An object of class `character` of length 28.

See Also

`example_prescriptions`

example_prescriptions *Example freetext prescriptions*

Description

Various examples of how prescription data may be represented in free text.

Usage

```
example_prescriptions
```

Format

An object of class `character` of length 27.

See Also

`example_cprd`

`extract_dose_unit` *Extract units of dose from freetext prescriptions.*

Description

A function used internally in `extract_from_prescription` to parse the dosage units, such as millilitres, tablets, grams and so on. If there are multiple units mentioned in a string, only the first is returned.

Usage

```
extract_dose_unit(txt)
```

Arguments

`txt`	a character vector

Value

A character vector the same length as `txt`, containing standardised units, or `NA` if no units were found in the prescription.

A simple wrapper around `str_replace_all` and `str_extract`. Based on `add_dose_unit.py` from original Python/Java algorithm.

See Also

`extract_from_prescription`

`extract_from_prescription` *Extract dosage information from free-text English-language prescriptions*

Description

This is the main workhorse function for the `doseminer` package. Pass in a character vector of prescribing instructions and it will extract structured dosage information.

Usage

```
extract_from_prescription(txt)
```

Arguments

`txt`	A character vector of freetext prescriptions

Details

To avoid redundant computation, it is recommended to remove duplicate elements from the input vector. The results can be joined back to the original data using the `raw` column.

Value

A `data.frame` with seven columns:

raw the input character vector

output a residual character vector of 'non-extracted' text. For debugging.

freq number of doses administered per day

itvl number of days between doses

dose quantity of medication in each dose

unit unit of measurement of medication, if any

optional integer. Can the dose be zero? 1 if yes, otherwise 0

Examples

```
extract_from_prescription(example_prescriptions)
```

`hourly_to_daily` *Convert hourly to daily frequency*

Description

Convert hourly to daily frequency

Usage

```
hourly_to_daily(txt)
```

Arguments

`txt`	String of the form 'every n hours'

Value

An equivalent string of the form 'x / day'

latin_medical_terms *List of Latin medical and pharmaceutical abbreviations*

Description

A named character vector. Names represent Latin terms and values the English translations. Used for converting terms like "q4h" into "every 4 hours", which can then be parsed into a dosage frequency/interval.

Usage

```
latin_medical_terms
```

Format

An object of class `character` of length 47.

Details

Use with a function like `str_replace_all` to translate a prescription from Latin to English (thence to numbers).

Source

https://en.wikipedia.org/wiki/List_of_abbreviations_used_in_medical_prescriptions

Examples

```
stringr::str_replace_all('Take two tablets q4h', latin_medical_terms)
```

multiply_dose *Evaluate a multiplicative plaintext expression*

Description

Replaces written phrases like "2 x 5" with their arithmetic result (i.e. 10)

Usage

```
multiply_dose(axb)
```

Arguments

axb	An string expression of the form 'A x B' where A, B are numeric

Value

An equivalent string giving the product of A and B. If A is a range of values, a range of values is returned.

See Also

Used internally within extract_from_prescription

---

numb_replacements *Dictionary of English names of numbers*

Description

For internal use in words2number. When passed as a replacement to a function like str_replace_all, it turns the string into an arithmetic expression that can be evaluated to give an integer representation of the named number.

Usage

```
numb_replacements
```

Format

An object of class character of length 49.

Details

Lifted from Ben Marwick's words2number package and converted into a named vector (previously a chain of gsub calls).

Note

Does not yet fully support decimals, fractions or mixed fractions. Some limited support for 'half' expressions, e.g. 'one and a half'.

Source

https://github.com/benmarwick/words2number

Examples

```
## Not run:
stringr::str_replace_all('one hundred and forty-two', numb_replacements)

## End(Not run)
```

regex_numbers *Regular expression to match numbers in English*

Description

A regex pattern to identify natural language English number phrases, such as "one hundred and fifty" or "thirty-seven". Used internally by `replace_numbers` to identify substrings to replace with their decimal representation.

Usage

```
regex_numbers
```

Format

An object of class `character` of length 1.

Details

This is a PCRE (Perl type) regular expression, so it must be used with `perl = TRUE` in base R regex functions. The packages `stringr` and `stringi` are based on the alternative ICU regular expression engine, so they cannot use this pattern.

Note

There is limited support for fractional expressions like "one half". The original pattern did not support expressions like "a thousand", but it has been adapted to offer (experimental) support for this. Phrases like "million" or "thousand" with no prefix will *not* match.

Source

https://www.rexegg.com/regex-trick-numbers-in-english.html

replace_numbers *Replace English number phrases with their decimal representations*

Description

Uses `numb_replacements` to match parts of a string corresponding to numbers, then invokes `words2number` to convert these substrings to numeric. The rest of the string (the non-number words) is left intact.

Usage

```
replace_numbers(string)
```

Arguments

string	A character vector. Can contain numbers and other text

Details

Works on non-negative integer numbers under one billion (one thousand million). Does not support fractions or decimals (yet).

Value

A character vector the same length as string, with words replaced by their decimal representations.

See Also

words2number, for use on cleaned text that does not contain any non-number words

Examples

```
replace_numbers('Two plus two equals four')
replace_numbers('one hundred thousand dollars!')
replace_numbers(c('A vector', 'containing numbers', 'like thirty seven'))
```

---

weekly_to_daily *Convert weekly interval to daily interval*

Description

Convert weekly interval to daily interval

Usage

```
weekly_to_daily(Dperweek)
```

Arguments

Dperweek	String of the form 'n / week'

Value

An equivalent string of the form 'x / day'

`words2number` *Convert English names of numbers to their numerical values*

Description

Convert English names of numbers to their numerical values

Usage

```
words2number(txt)
```

Arguments

`txt`	A character vector containing names of numbers (only).

Value

A named numeric vector of the same length as `phrase`.

Source

Originally adapted from the `words2number` package by Ben Marwick.

Examples

```
words2number('seven')
words2number('forty-two')
words2number(c('three', 'one', 'twenty two thousand'))
```
